

(a) One forecast per patient, unchanged across days

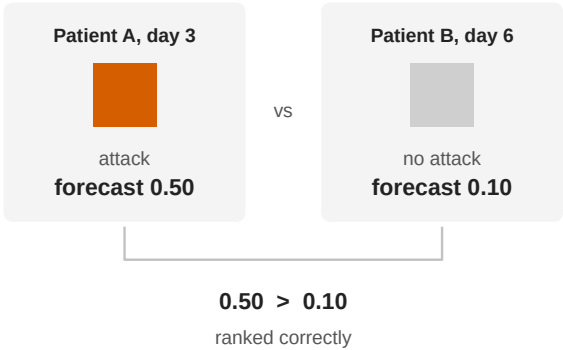

A forecast is the model's estimated chance that a given day turns out to be an attack day.

Patient A records attacks on 5 of 10 days, patient B on 1 of 10. Each forecast here is set to that patient's own recorded rate, so it never changes from day to day.

Outlined days are compared below.

(b) Pooled AUROC compares days across patients

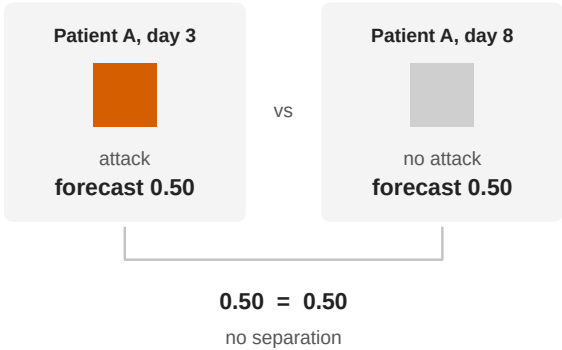

Attack frequency decides this comparison.
Neither day was examined.

45 of 84 comparisons cross patients.

AUROC **0.74**

(c) Within-person C compares one patient's days

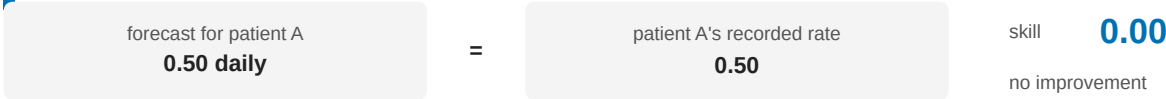

The clinically relevant comparison.
The forecast is identical on both days.

All 34 within-patient comparisons tie.

C **0.50**

(d) Brier skill: does the forecast improve on the known rate?

The two are the same number by construction. Skill of zero is what a forecast that adds nothing looks like.
