

The model gives each patient one risk and never varies it day to day, so it carries no information about which day an attack falls on.

Pooled AUROC compares every attack day with every quiet day, whoever they belong to

45 of the 84 comparisons are between patients and the model wins them, 5 it loses, and the 34 inside a patient are all ties

AUROC 0.74 carried by the between-patient comparisons

The within-person C-statistic keeps only the comparisons inside a patient

the same 34 ties, and nothing else left to score

C 0.50 chance: the model never ranked one of a patient's own days above another
