

(a) A classifier that emits each patient's own attack rate

The bracket is the point: one value covers all ten days, so the forecast says nothing about which day an attack falls on.

(b) Every attack-day / quiet-day pair, one square each

(c) The same squares, restacked: each score is a position

The pointer sits at the concordant squares plus half the tied ones. Within a patient there are no concordant squares at all, so it lands mid-tie: chance.

(d) Brier skill: squared error against the patient's own rate
