

1 Can it rank attack days across the cohort?

Pooled AUROC: every patient's days placed in one ranking.

2 Can it rank days inside one patient?

Within-person C-statistic: the same test, run inside each diary.

3 Does it beat the patient's own attack rate?

Brier skill against each patient's recorded rate.

4 Would acting on it help the patient?

Decision-curve net benefit against the two default policies.

Pooled AUROC is the endpoint most often reported for this task. Read on its own it supports a usable forecast; read alongside the three questions that follow it does not, and neither target retains that support as far as a clinical decision on diary-only data from this cohort.
